1 Introduction

This is a summary of the course “Algebra des Programmierens” taught by Prof. Dr. Stefan Milius in the winter term 2023/2024 at the FAU ¹. The course is based on [2] with [1] as a reference for category theory.

Goal of the course is to develop a mathematical theory for semantics of data types and their accompanying proof principles. The chosen environment is the field of category theory.

1.1 Functions

A function $f : X \rightarrow Y$ is a mapping from the set X (the domain of f) to the set Y (the codomain of f). More concretely f is a relation $f \subseteq X \times Y$ which is

- *left-total*, i.e. for all $x \in X$ exists some $y \in Y$ such that $(x, y) \in f$;
- *right-unique*, i.e. any $(x, y), (x, y') \in f$ imply $y = y'$.

Often, one is also interested in the symmetrical properties, a function is called

- *injective* or *left-unique* if for every $x, x' \in X$ the implication $f(x) = f(x') \rightarrow x = x'$ holds;
- *surjective* or *right-total* if for every $y \in Y$ there exists an $x \in X$ such that $f(x) = y$;
- *bijective* if it is injective and surjective.

Example 1.1.1. 1. The identity function $id_A : A \rightarrow A$, $id_A(x) = x$

2. The constant function $b! : A \rightarrow B$ for $b \in B$ defined by $b!(x) = b$

3. The inclusion function $i_A : A \rightarrow B$ for $A \subseteq B$ defined by $i_A(x) = x$

4. Constants $b : 1 \rightarrow B$, where $1 := *$. The function b is in bijection with the set B .

5. Composition of function $f : A \rightarrow B, g : B \rightarrow C$ called $g \circ f : A \rightarrow C$ defined by $(g \circ f)(x) = g(f(x))$.

6. The empty function $\jmath : \emptyset \rightarrow B$

7. The singleton function $! : A \rightarrow 1$

1.2 Data Types

Programs work with data that should ideally be organized in a useful manner. A useful representation for data in functional programming is by means of *algebraic data types*. Some basic data types (written in Haskell notation) are

- 1 **data Bool = True | False**
- 2 **data Nat = Zero | Succ Nat**

¹Friedrich-Alexander-Universität Erlangen-Nürnberg

These data types are declared by means of constructors, yielding concrete descriptions how inhabitants of these types are created. *Parametric data types* are additionally parametrized by another data type, e.g.

```

1 data Maybe a = Nothing | Just a
2 data Either a b = Left a | Right b
3 data List a = Nil | Cons a (List a)

```

Such data types (parametric or non-parametric) usually come with a principle for defining functions called recursion and in richer type systems (e.g. in a dependently typed setting) with a principle for proving facts about recursive functions called induction. Equivalently, every function defined by recursion can be defined via a *fold*-function which satisfies an identity and fusion law, which replace the induction principle. Let us now consider two examples of data types and illustrate this.

1.2.1 Natural Numbers

The type of natural numbers comes with a fold function $foldn : C \rightarrow (Nat \rightarrow C) \rightarrow Nat \rightarrow C$ for every C , defined by

$$\begin{aligned}
 foldn\ c\ h\ zero &= c \\
 foldn\ c\ h\ (suc\ n) &= h\ (foldn\ c\ h\ n)
 \end{aligned}$$

Example 1.2.1. Let us now consider some functions defined in terms of $foldn$.

- $iszero : Nat \rightarrow Bool$ is defined by

$$iszero = foldn\ true\ false!$$

- $plus : Nat \rightarrow Nat \rightarrow Nat$ is defined by

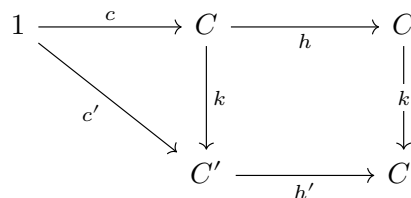

$$plus = foldn\ id\ (succ \circ eval)$$

where $eval : (A \rightarrow B) \rightarrow A \rightarrow B$ is defined by

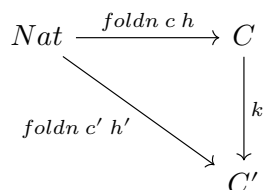

$$eval\ f\ a = f\ a$$

Proposition 1.2.2. $foldn$ satisfies the following two rules

1. **Identity:** $foldn\ zero\ succ = id_{Nat}$
2. **Fusion:** for all $c : C$, $h, h' : Nat \rightarrow C$ and $k : C \rightarrow C'$ with $kc = c'$ and $kh = h'k$ follows $k \circ foldn\ c\ h = foldn\ c'\ h'$, or diagrammatically:

implies

Proof. Both follow by induction over an argument $n : \text{Nat}$:

1. **Identity:**

Case 1. $n = \text{zero}$

$$\text{foldn zero succ zero} = \text{zero} = \text{id zero}$$

Case 2. $n = \text{succ } m$

$$\begin{aligned} \text{foldn zero succ (succ } m) &= \text{succ}(\text{foldn zero succ } m) \\ &= \text{succ } m \\ &= \text{id}(\text{succ } m) \end{aligned} \tag{IH}$$

2. **Fusion:**

Case 1. $n = \text{zero}$

$$k(\text{foldn } c \ h \ \text{zero}) = k \ c = c' = \text{foldn } c' \ h' \ \text{zero}$$

Case 2. $n = \text{succ } m$

$$\begin{aligned} k(\text{foldn } c \ h \ (\text{succ } m)) &= k(h(\text{foldn } c \ h \ m)) \\ &= h'(k(\text{foldn } c \ h \ m)) \\ &= h'(\text{foldn } c' \ h' \ m) \\ &= \text{foldn } c' \ h' \ (\text{succ } m) \end{aligned} \tag{IH}$$

□

Example 1.2.3. The identity and fusion laws can in turn be used to prove the following induction principle:

For any predicate $p : \text{Nat} \rightarrow \text{Bool}$,

1. $p \ \text{zero} = \text{true}$ and
2. $p \circ \text{succ} = p$

implies $p = \text{true!}$. This follows by

$$\begin{aligned} &p \\ &= p \circ (\text{foldn zero succ}) && \text{(Identity)} \\ &= \text{foldn true id} && \text{(Fusion)} \\ &= \text{true!} \circ (\text{foldn zero succ}) && \text{(Fusion)} \\ &= \text{true!}. && \text{(Identity)} \end{aligned}$$

Where the first application of **Fusion** is justified, since the diagram

$$\begin{array}{ccccc} 1 & \xrightarrow{\text{zero}} & \text{Nat} & \xrightarrow{\text{succ}} & \text{Nat} \\ & \searrow \text{true} & \downarrow p & & \downarrow p \\ & & \text{Bool} & \xrightarrow{\text{id}} & \text{Bool} \end{array}$$

commutes by the requisite properties of p , and the second application of **Fusion** is justified, since the diagram

$$\begin{array}{ccccc}
 1 & \xrightarrow{\text{zero}} & \text{Nat} & \xrightarrow{\text{succ}} & \text{Nat} \\
 & \searrow \text{true} & \downarrow \text{true!} & & \downarrow \text{true!} \\
 & & \text{Bool} & \xrightarrow{\text{id}} & \text{Bool}
 \end{array}$$

trivially commutes.

1.2.2 Lists

We will now look at the *List* type and examine it for similar properties. Let us start with the fold function $\text{foldr} : C \rightarrow (A \rightarrow C \rightarrow C) \rightarrow \text{List } A \rightarrow C$, which is defined by

$$\begin{aligned}
 \text{foldr } c \ h \ \text{nil} &= c \\
 \text{foldr } c \ h \ (\text{cons } x \ xs) &= h \ a \ (\text{foldr } c \ h \ xs)
 \end{aligned}$$

Example 1.2.4. Again, let us define some functions using *foldr*.

- $\text{length} : \text{List } A \rightarrow \text{Nat}$ is defined by

$$\text{length} = \text{foldr } \text{zero} \ (\text{succ!})$$

- For $f : A \rightarrow B$ we can define *List*-mapping function $\text{List } f : \text{List } A \rightarrow \text{List } B$ by

$$\text{List } f = \text{foldr } \text{nil} \ (\text{cons} \circ f)$$

Proposition 1.2.5. *foldr* satisfies the following two rules

1. **Identity:** $\text{foldr } \text{nil} \ \text{cons} = \text{id}_{\text{List } A}$
2. **Fusion:** for all $c : C$, $h, h' : \text{Nat}$

2 Category Theory

Categories consist of objects and morphisms between those objects, that can be composed in a coherent way. This yields a framework for abstraction of many mathematical concepts that enables us to reason on a very abstract level.

Definition 2.0.1 (Category). A category \mathcal{C} consists of

- a class of objects denoted $|\mathcal{C}|$,
- for every pair of objects $A, B \in |\mathcal{C}|$ a set of morphisms $\mathcal{C}(A, B)$ called the hom-set,
- a morphism $id_A : A \rightarrow A$ for every $A \in |\mathcal{C}|$
- a composition operator $(-) \circ (-) : \mathcal{C}(B, C) \rightarrow \mathcal{C}(A, B) \rightarrow \mathcal{C}(A, C)$ for every $A, B, C \in |\mathcal{C}|$

additionally the composition must be associative and $f \circ id_A = f = id_B \circ f$ for any $f : A \rightarrow B$.

Example 2.0.2. Some standard examples of categories and their objects and morphisms include:

Category	Objects	Morphisms
Set	Sets	Functions
Par	Sets	Partial functions
Rel	Sets	Binary relations
Gra	Directed Graphs	Graph homomorphisms
Pos	Partially ordered sets	Monotone mappings
Mon	Monoids	Monoid homomorphisms
Monoid (M, \cdot, e)	A single object $*$	$x : * \rightarrow *$ for every $x \in M$
Poset (X, \leq)	Elements of X	$x \leq y \iff \exists ! f : x \rightarrow y$

2.1 Special Objects

Special objects play an important role in category theory. In this chapter we will characterize (finite) products and coproducts, as well as special morphisms such as isomorphisms, monomorphisms and epimorphisms.

2.2 Initial and Terminal Objects

Definition 2.2.1 (Initial and Terminal Objects). The following is the categorical abstraction of “empty set” and “singleton set” respectively.

1. An object $0 \in |\mathcal{C}|$ is called initial if for every $B \in |\mathcal{C}|$ there is a unique morphism $! : 0 \rightarrow B$.
2. An object $1 \in |\mathcal{C}|$ is called terminal if for every $A \in |\mathcal{C}|$ there is a unique morphism $! : A \rightarrow 1$.

Example 2.2.2. Oftentimes the initial object is an empty structure and the terminal object a singleton structure, some examples are:

Category	Initial Object	Terminal Object
Set	\emptyset	*
Pos	\emptyset	*
Gra	Empty graph	Singleton graph
Poset (X, \leq)	$\perp \in X$ such that $\forall x \in X. \perp \leq x$	$\top \in X$ such that $\forall x \in X. x \leq \top$

2.3 Special Morphisms

Now let us characterize special morphisms.

Definition 2.3.1 (Special Morphisms). Let $f : A \rightarrow B$ be a morphism. f is called

- an *isomorphism* (*iso*), if there exists an inverse $f^{-1} : B \rightarrow A$ such that $f \circ g = id_B$ and $g \circ f = id_A$;
- a *monomorphism* (*mono*), if for all $g, h : C \rightarrow A$ the implication $f \circ g = f \circ h \Rightarrow g = h$ holds;
- an *epimorphism* (*epi*), if for all $g, h : B \rightarrow C$ the implication $g \circ f = h \circ f \Rightarrow g = h$ holds.

Example 2.3.2. Let us consider what these notions instantiate to in concrete categories.

Category	Monomorphisms	Epimorphisms	Isomorphisms
Set	injective functions	surjective functions	bijective functions
Pos, Gra	injective morphisms	surjective morphisms	bijective morphisms
Poset (X, \leq)	all	all	all
Monoid (M, \cdot, e)	left cancellative $a \in M$	right cancellative $a \in M$	invertible $a \in M$

Proposition 2.3.3. *Every isomorphism is a monomorphism and an epimorphism.*

Proof. Let f be an isomorphism.

- $f \circ g = f \circ h$ implies $g = f^{-1} \circ f \circ g = f^{-1} \circ f \circ h = h$, thus f is a monomorphism.
- $g \circ f = h \circ f$ implies $g = g \circ f \circ f^{-1} = h \circ f \circ f^{-1} = h$, thus f is an epimorphism.

□

Proposition 2.3.4. *If $f \circ m$ is a monomorphism then m is also a monomorphism.*

Proof. Let $m \circ g = m \circ h$. To show that $g = h$ it suffices to show that $f \circ m \circ g = f \circ m \circ h$, which indeed follows by assumption. □

Proposition 2.3.5. *If $e \circ f$ is an epimorphism then e is also an epimorphism.*

Proof. Let $g \circ e = h \circ e$. To show that $g = h$ it suffices to show that $g \circ e \circ f = h \circ e \circ f$, which again follows by assumption. □

Categorical structures like initial objects are usually not uniquely identified, there might be multiple initial objects in a category. However, all initial objects in a category are isomorphic, we call this “unique up to isomorphism”.

Proposition 2.3.6. *Initial objects are unique up to isomorphism.*

Proof. Let $0, 0' \in |\mathcal{C}|$ be two initial objects of \mathcal{C} with the unique morphisms $i_A : 0 \rightarrow A$ and $i'_A : 0' \rightarrow A$. The isomorphism is:

$$\begin{array}{ccc} & i_{0'} & \\ 0 & \xrightarrow{\quad} & 0' \\ & i'_{0'} & \\ & \xleftarrow{\quad} & \end{array}$$

Note that by uniqueness $i_{0'} \circ i'_{0'} = i'_{0'} = id_{0'}$ and $i'_{0'} \circ i_0 = i_0 = id_0$. □

Proposition 2.3.7. *Terminal objects are unique up to isomorphism.*

Proof. Let $1, 1' \in |\mathcal{C}|$ be two terminal objects of \mathcal{C} with the unique morphisms $!_A : A \rightarrow 1$ and $!'_A : A \rightarrow 1'$. The isomorphism is:

$$\begin{array}{ccc} & !_1 & \\ 1 & \xrightarrow{\quad} & 1' \\ & !_1' & \\ & \xleftarrow{\quad} & \end{array}$$

Note that by uniqueness $!_1 \circ !_1' = !_1' = id_{1'}$ and $!_1' \circ !_1 = !_1 = id_1$. □

2.4 Duality

Notice how similar the proofs of Proposition 2.3.4 and Proposition 2.3.5 as well as Proposition 2.3.6 and Proposition 2.3.7 are to each other. It seems that we should somehow be able to construct one proof from the other, such that the work required would be halved. This is actually the case, we can for example say that Proposition 2.3.5 follows from Proposition 2.3.4 by *duality*.

Definition 2.4.1 (Dual Category). Every category \mathcal{C} has a *dual category* \mathcal{C}^{op} defined by

- $|\mathcal{C}^{op}| = |\mathcal{C}|$
- $\mathcal{C}^{op}(A, B) = \mathcal{C}(B, A)$

Example 2.4.2. Examples are:

1. In a poset the order relation gets reversed.
2. Rel^{op} is isomorphic to Rel , since subsets of $A \times B$ are in bijection with subsets of $B \times A$
3. $(\mathcal{C}^{op})^{op} = \mathcal{C}$

Every categorical notion can thus be dualized by viewing it in the dual category, some examples include:

Notion	Dual Notion
Initial Object	Terminal Object
Monomorphism	Epimorphism
Isomorphism	Isomorphism

This yields a proof principle “by duality”, where every theorem yields another theorem by duality.

2.5 Products and Coproducts

The categorical abstraction of Cartesian products is:

Definition 2.5.1 (Product). The *product* of two objects $A, B \in |\mathcal{C}|$ is an object that we call $A \times B$ together with morphisms $\pi_1 : A \times B \rightarrow A$ and $\pi_2 : A \times B \rightarrow B$ (the projections), where the following property holds:

$$\begin{array}{ccccc}
 & & C & & \\
 & \swarrow f & \vdots \exists!(f,g) & \searrow g & \\
 A & \xleftarrow{\pi_1} & A \times B & \xrightarrow{\pi_2} & B
 \end{array}$$

Example 2.5.2. Some examples include:

1. **Set:** The product of two sets A and B is the Cartesian product $A \times B = \{(a, b) \mid a \in A, b \in B\}$.
2. **Gra:** The product of two graphs has as vertices the Cartesian product of the vertices of both graphs and an edge $(v_1, u_1) \rightarrow (v_2, u_2)$ iff there exists edges $v_1 \rightarrow v_2$ and $u_1 \rightarrow u_2$.
3. **Pos:** Given two posets $(A, \leq), (B, \leq)$, the product is the Cartesian product of A and B where $(a, b) \leq (a', b') \iff a \leq a' \wedge b \leq b'$.
4. Let (X, \leq) be a poset, the product of $a, b \in X$ is the greatest lower bound of a and b .

Dual to products are:

Definition 2.5.3 (Coproduct). The *coproduct* of two objects $A, B \in |\mathcal{C}|$ is an object that we call $A + B$ together with morphisms $i_1 : A \rightarrow A + B$ and $i_2 : B \rightarrow A + B$ (the injections), where the following property holds:

$$\begin{array}{ccccc}
 A & \xrightarrow{i_1} & A + B & \xleftarrow{i_2} & B \\
 & \searrow f & \vdots \exists!(f,g) & \swarrow g & \\
 & & C & &
 \end{array}$$

Example 2.5.4. Examples include:

1. **Set:** The coproduct of two sets A and B is the disjoint union $A + B = \{(a, 0) \mid a \in A\} \cup \{(b, 1) \mid b \in B\}$.
2. **Pos:** The coproduct of ordered sets (A, \leq) and (B, \leq) is the disjoint union $A + B$ where $z \leq z'$ iff $z, z' \in A$ and $z \leq z'$ or $z, z' \in B$ and $z \leq z'$.
3. **Gra:** Analogous to **Pos**.
4. Let (X, \leq) be a poset, the coproduct of $a, b \in X$ is the least upper bound of a and b .

5. Rel: Analogous to Set the coproduct is the disjoint union. Since $\text{Rel} \cong \text{Rel}^{op}$ we know that the product is also the disjoint union.

Proposition 2.5.5. *Products are unique up to isomorphism.*

Proof. The usual proof is somewhat analogous to the proof of Proposition 2.3.7. Instead, we will prove it like this:

Consider the category $\text{span}_{\mathcal{C}}(A, B)$ where objects are triples $A \xleftarrow{f} C \xrightarrow{g} B$ and morphisms $(C, f, g) \rightarrow (C', f', g')$ are morphisms $k : C \rightarrow C'$ in \mathcal{C} such that

$$\begin{array}{ccc}
 & C & \\
 f \swarrow & & \searrow g \\
 A & & B \\
 f' \swarrow & & \searrow g' \\
 & C' &
 \end{array}$$

commutes. Products of A and B are the final objects in $\text{span}_{\mathcal{C}}(A, B)$ and are thus unique up to isomorphism. \square

By duality, we get:

Proposition 2.5.6. *Coproducts are unique up to isomorphism.*

We can now characterize products (and later dually coproducts) as a commutative monoid:

Proposition 2.5.7. *1 is a unit of \times , i.e. $A \cong A \times 1$ for any $A \in |\mathcal{C}|$.*

Proof. Take $\langle id_A, !_A \rangle : A \rightarrow A \times 1$ and $\pi_1 : A \times 1 \rightarrow A$, this indeed constitutes an isomorphism, since

$$\pi_1 \circ \langle id_A, !_A \rangle = id_A$$

by definition and

$$\langle id_A, !_A \rangle \circ \pi_1 = \langle \pi_1, !_A \rangle = \langle \pi_1, \pi_2 \rangle = id_{A \times 1},$$

because $\pi_2 = !_A : A \times 1 \rightarrow 1$ by uniqueness of $!_A$. \square

Proposition 2.5.8. *\times is associative, i.e. $A \times (B \times C) \cong (A \times B) \times C$ for any $A, B, C \in |\mathcal{C}|$.*

Proof. Take

$$\alpha = \langle \langle \pi_1, \pi_1 \circ \pi_2 \rangle, \pi_2 \circ \pi_2 \rangle : A \times (B \times C) \rightarrow (A \times B) \times C$$

and

$$\alpha^{-1} = \langle \pi_1 \circ \pi_1, \langle \pi_2 \circ \pi_1, \pi_2 \rangle \rangle : (A \times B) \times C \rightarrow A \times (B \times C).$$

The rest of the proof then amounts to simply rewriting. \square

Proposition 2.5.9. *\times is commutative, i.e. $A \times B \cong B \times A$ for any $A, B \in |\mathcal{C}|$.*

Proof. Take

$$\langle \pi_2, \pi_1 \rangle : A \times B \rightarrow B \times A$$

and

$$\langle \pi_2, \pi_1 \rangle : B \times A \rightarrow A \times B.$$

Indeed, $\langle \pi_2, \pi_1 \rangle \circ \langle \pi_2, \pi_1 \rangle = \langle \pi_2 \circ \langle \pi_2, \pi_1 \rangle, \pi_1 \circ \langle \pi_2, \pi_1 \rangle \rangle = \langle \pi_1, \pi_2 \rangle = id.$ □

Duality instantly yields the commutative monoid structure of coproducts:

Proposition 2.5.10. 0 is the unit of $+$, i.e. $A \cong A + 0$ for any $A \in |\mathcal{C}|$.

Proposition 2.5.11. $+$ is associative, i.e. $A + (B + C) \cong (A + B) + C$ for any $A, B, C \in |\mathcal{C}|$.

Proposition 2.5.12. $+$ is commutative, i.e. $A + B \cong B + A$ for any $A, B \in |\mathcal{C}|$.

Remark 2.5.13. If a category has a terminal object and binary products one can form arbitrary n -ary products (finite products), such a category is called *Cartesian*. Dually a category with an initial object and binary coproducts is called *Cocartesian*.

2.6 Functors

Functors are morphisms between categories, concretely:

Definition 2.6.1 (Functor). A functor $F : \mathcal{C} \rightarrow \mathcal{D}$ consists of

- a mapping $F : |\mathcal{C}| \rightarrow |\mathcal{D}|$ on objects and
- a mapping $F : \mathcal{C}(A, B) \rightarrow \mathcal{C}(FA, FB)$ on morphisms,

such that $F(id_A) = id_{FA}$ and $F(g \circ f) = Fg \circ Ff$.

Example 2.6.2. Usual examples of functors include

1. Constant functors mapping to a single object: $D! : \mathcal{C} \rightarrow \mathcal{D}, D \in |\mathcal{D}|$ with

$$D!(C) = D, \quad D!(f) = id_D.$$

2. Identity functor: $Id_{\mathcal{C}} : \mathcal{C} \rightarrow \mathcal{C}$ with

$$Id_{\mathcal{C}}(C) = C, \quad Id_{\mathcal{C}}(f) = f.$$

3. Composition of functors: $(FG)(X) = F(GX), (FG)(f) = F(Gf)$

4. Square functor on **Set**: $Q : \mathbf{Set} \rightarrow \mathbf{Set}$ with

$$QX = X \times X, \quad Qf = f \times f.$$

5. $list : \mathbf{Set} \rightarrow \mathbf{Set}$, see subsection 1.2.2.

6. For $A \in |\mathcal{C}|$ there is the hom-functor $\mathcal{C}(A, -) : \mathcal{C} \rightarrow \mathbf{Set}$ given by

$$\mathcal{C}(A, B), \quad \mathcal{C}(A, f : B \rightarrow B')(h : A \rightarrow B) = f \circ h : \mathcal{C}(A, B').$$

7. Functors between posets are monotonous maps, which in turn are the morphisms in **Pos**.

8. Functors between monoids are monoid homomorphisms, which in turn are the morphisms in \mathbf{Mon} .
9. The power set functor $\mathcal{P} : \mathbf{Set} \rightarrow \mathbf{Set}$ defined by

$$\begin{aligned}\mathcal{P}X &= \{Y \mid Y \subseteq X\} \\ (\mathcal{P}f)Y &= f[Y] \subseteq X', \text{ for } Y \subseteq X.\end{aligned}$$

10. If \mathcal{C} is a category that adds some structure to sets (like \mathbf{Mon} or \mathbf{Pos}) one usually can construct a *forgetful functor* $U : \mathcal{C} \rightarrow \mathbf{Set}$, e.g.

$$\begin{aligned}U_{\mathbf{Pos}} : \mathbf{Pos} &\rightarrow \mathbf{Set}; & (X, \leq) &\mapsto X \\ U_{\mathbf{Mon}} : \mathbf{Mon} &\rightarrow \mathbf{Set}; & (M, \cdot, e) &\mapsto M\end{aligned}$$

Using functors as morphisms, one can *almost* build a category CAT of *all* categories, however the collection of all categories is not a class (as required) but a *conglomerate*, thus CAT is called a *quasi-category*. The small categories (i.e. where the collection of objects is a set) form a ‘real’ category Cat .

We can however consider structures like products and isomorphisms in the quasi-category CAT :

Definition 2.6.3 (Products of Categories). The product of two categories \mathcal{C}, \mathcal{D} consists of

- $|\mathcal{C} \times \mathcal{D}| = |\mathcal{C}| \times |\mathcal{D}|$,
- $(\mathcal{C} \times \mathcal{D})((A_1, A_2), (B_1, B_2)) = \mathcal{C}(A_1, B_1) \times \mathcal{D}(A_2, B_2)$,

with projection functors $\pi_1 : \mathcal{C} \times \mathcal{D} \rightarrow \mathcal{C}, \pi_2 : \mathcal{C} \times \mathcal{D} \rightarrow \mathcal{D}$.

Example 2.6.4. More examples of functors include:

11. The Cartesian product functor: $- \times - : \mathbf{Set} \times \mathbf{Set} \rightarrow \mathbf{Set}$.
12. The binary hom-functor $\mathcal{C}(-, -) : \mathcal{C}^{op} \times \mathcal{C} \rightarrow \mathbf{Set}$ with

$$\mathcal{C}(A, B), \quad \mathcal{C}(g : X' \rightarrow X, f : Y \rightarrow Y')(h : X \rightarrow Y) = f \circ h \circ g : \mathcal{C}(X', Y').$$

Definition 2.6.5 (Covariant and Contravariant Functors). A functor $F : \mathcal{C}^{op} \rightarrow \mathcal{D}$ is called a *contravariant* functor $\mathcal{C} \rightarrow \mathcal{D}$. For differentiation, we call ‘normal’ functors $\mathcal{C} \rightarrow \mathcal{D}$ *covariant*.

Example 2.6.6. Examples of contravariant functors include:

13. For every $Y \in |\mathcal{C}|$ there is a contravariant hom-functor $\mathcal{C}(-, Y) : \mathcal{C}^{op} \rightarrow \mathbf{Set}$ given by

$$\mathcal{C}(X, Y), \quad \mathcal{C}(f : X' \rightarrow X, Y)(h : X \rightarrow Y) = h \circ f : \mathcal{C}(X', Y).$$

14. $2^{(-)} : \mathbf{Set}^{op} \rightarrow \mathbf{Set}$ where

$$2^X = \{f : X \rightarrow 2\} \cong \mathcal{P}X$$

and

$$2^{(f : X \rightarrow Y)} : 2^Y \rightarrow 2^X \cong \mathcal{P}Y \rightarrow \mathcal{P}X, \quad Z \mapsto \{x \mid fx \in Z\} = f^{-1}[Z] \subseteq X.$$

15. For every functor $F : \mathcal{C} \rightarrow \mathcal{D}$ the identical functor $F^{op} : \mathcal{C}^{op} \rightarrow \mathcal{D}^{op}$, given by

$$F^{op}C = FC, \quad F^{op}f = Ff.$$

Isomorphisms of categories are the isomorphisms in the quasi-category CAT , thus a functor is an isomorphism iff he is bijective on both objects and morphisms. However, oftentimes categories are not isomorphic but instead *equivalent* in the following sense:

Definition 2.6.7 (Equivalence Functors). A functor $F : \mathcal{C} \rightarrow \mathcal{D}$ is called

- *full* if every $F : \mathcal{C}(A, B) \rightarrow \mathcal{D}(FA, FB)$ is surjective,
- *faithful* if every $F : \mathcal{C}(A, B) \rightarrow \mathcal{D}(FA, FB)$ is injective,
- *essentially surjective (dense)* if for every $D \in \mathcal{D}$ there exists a $C \in \mathcal{C}$ such that $D \cong FC$,
- an *equivalence* if F is full, faithful and dense.

Example 2.6.8. Let us consider two examples of equivalent categories:

1. The category \mathbf{Par} is equivalent to \mathbf{Set}_p , which is the category of pointed sets, where objects are tuples $(X, p), p \in X$ and morphisms are point-preserving.
2. The product category $\mathbf{Set} \times \mathbf{Set}$ is equivalent to the *slice category* $\mathbf{Set}/2$, where objects are maps $X \rightarrow 2$ and morphisms $h : (X \xrightarrow{f} 2) \rightarrow (Y \xrightarrow{g} 2)$ are maps $h : X \rightarrow Y$ such that $g \circ h = f$.

2.7 Natural Transformations

Natural transformation are morphisms between functors. The definition of “naturality” was one of the original goals of category theory.

Definition 2.7.1 (Natural Transformation). Given two functors $F, G : \mathcal{C} \rightarrow \mathcal{D}$. A natural transformation $\alpha : F \rightarrow G$ between these functors is a family of morphisms

$$(\alpha_C : FC \rightarrow GC)_{C \in |\mathcal{C}|},$$

such that for any $f : A \rightarrow B$ the diagram

$$\begin{array}{ccc} FA & \xrightarrow{Ff} & FB \\ \alpha_A \downarrow & & \downarrow \alpha_B \\ GA & \xrightarrow{Gf} & GB \end{array}$$

commutes.

Example 2.7.2. Examples of natural transformations include:

1. The obvious function $flatten : Tree A \rightarrow List A$:

$$\begin{array}{ccc} Tree A & \xrightarrow{tree f} & Tree B \\ flatten_A \downarrow & & \downarrow flatten_B \\ List A & \xrightarrow{list f} & List B \end{array}$$

2. For $Id, Q : Set \rightarrow Set$ we have $\delta : Id \rightarrow Q$ given by $\delta_X(x) = (x, x)$.

3. On \mathcal{P} we can define natural transformations $\eta : \text{Id} \rightarrow \mathcal{P}$ and $\mu : \mathcal{P}\mathcal{P} \rightarrow \mathcal{P}$ by:

$$\begin{aligned} \eta_X : X &\rightarrow \mathcal{P}X \\ x &\mapsto \{x\} \end{aligned}$$

and

$$\begin{aligned} \mu_X : \mathcal{P}\mathcal{P}X &\rightarrow \mathcal{P}X \\ Z &\mapsto \bigcup Z. \end{aligned}$$

4. Between \mathcal{Q} and \mathcal{P} we can consider $\alpha, \beta : \mathcal{Q} \rightarrow \mathcal{P}$ given by

$$\begin{aligned} \alpha_X(x, y) &= \{x, y\} \\ \beta_X(x, y) &= \{x\}. \end{aligned}$$

Functors $\mathcal{C} \rightarrow \mathcal{D}$ together with natural transformations as morphisms form a quasi-category $[\mathcal{C}, \mathcal{D}]$, that is called the functor category. If \mathcal{C} is small, then $[\mathcal{C}, \mathcal{D}]$ is a category, where identity and composition are defined component wise.

Example 2.7.3. Let us examine concrete examples of functor categories:

1. $[2, \mathcal{C}] \cong \mathcal{C} \times \mathcal{C}$, where 2 is the *discrete* category with two objects, i.e. 2 has no morphisms besides the identities.
2. Let \rightarrow be the category with 2 objects and a single non-trivial morphism m . $[\rightarrow, \mathcal{C}]$ is the *category of morphisms* of \mathcal{C} , where morphisms $Fm \rightarrow Gm$ are pairs of morphisms (f, g) where

$$\begin{array}{ccc} F0 & \xrightarrow{Fm} & F1 \\ \downarrow f & & \downarrow g \\ G0 & \xrightarrow{Gm} & G1 \end{array}$$

commutes.

Definition 2.7.4 (Natural Isomorphism). Isomorphisms in $[\mathcal{C}, \mathcal{D}]$ are called *natural isomorphisms*.

Proposition 2.7.5. $\alpha : F \rightarrow G$ is a natural isomorphism iff every α_C is an isomorphism.

Example 2.7.6. Let us consider some examples of natural isomorphisms:

1. In $[\text{Set}, \text{Set}]$ is $\text{Id} \cong \text{Set}(1, -)$, since of course $\text{Id } X = X \cong X^1 = \text{Set}(1, X)$.
2. Also in $[\text{Set}, \text{Set}]$ is $Q \cong \text{Set}(2, -)$, similarly is $\lambda X. 2 \times X \cong \lambda X. X + X$.
3. The forgetful functor $U : \text{Pos} \rightarrow \text{Set}$ is naturally isomorphic to $\text{Pos}(1, -)$, because the constant mapping $x : 1 \rightarrow X$ is monotonous for every element x of a poset.

Proposition 2.7.7 (Yoneda Lemma). Let $A \in |\mathcal{C}|$ and $G : \mathcal{C} \rightarrow \text{Set}$. Then the natural transformations

$$\mathcal{C}(A, -) \rightarrow G$$

are in bijection with the elements of the set GA . In other words

$$[\mathcal{C}, \text{Set}](\mathcal{C}(A, -), G) \cong GA$$

Proof. The mappings are

$$\begin{aligned} Z : GA &\rightarrow [\mathcal{C}, \mathbf{Set}](\mathcal{C}(A, -), G) \\ Z x h &= G h x \end{aligned}$$

and

$$\begin{aligned} Y : [\mathcal{C}, \mathbf{Set}](\mathcal{C}(A, -), G) &\rightarrow GA \\ Y \alpha &= \alpha_A id_A. \end{aligned}$$

We are left to check naturality of $Z x$ and that indeed Z and Y are inverse to each other, all of which follows by routine rewriting. \square

Example 2.7.8. Let us consider an application of the Yoneda Lemma: how many natural transformations $\text{Id} \rightarrow Q$ are there? Recall that $\text{Id} \cong \mathbf{Set}(1, -)$, and by Yoneda there is exactly $|Q1| = 1$ natural transformation $\mathbf{Set}(1, -) \rightarrow Q$, thus the number of natural transformations $\text{Id} \rightarrow Q$ is 1.

Furthermore, consider the number of natural transformations $Q \rightarrow Q$. Recall that $Q \cong \mathbf{Set}(2, -)$, and by Yoneda there are $|Q2| = 4$ natural transformations $\mathbf{Set}(2, -) \rightarrow Q$, thus the number of natural transformations $Q \rightarrow Q$ is 4.

2.8 Functor Algebras

Recall the fold functions that we introduced in chapter 1 in the category \mathbf{Set} :

$$\begin{aligned} foldn : (1 \rightarrow C) &\rightarrow (C \rightarrow C) \rightarrow Nat \rightarrow C \\ foldr : (1 \rightarrow C) &\rightarrow (A \times C \rightarrow C) \rightarrow List A \rightarrow C \end{aligned}$$

These are examples of special *F-algebras* in \mathbf{Set} . In this section we will introduce this notion and examine what makes the fold functions special.

Definition 2.8.1 (F-Algebras). Let $F : \mathcal{C} \rightarrow \mathcal{C}$ be an endofunctor on \mathcal{C} . An *F-algebra* is a pair $(A \in |\mathcal{C}|, a : FA \rightarrow A)$. Homomorphisms between F-algebras (A, a) and (B, b) are morphisms $f : A \rightarrow B$ such that

$$\begin{array}{ccc} FA & \xrightarrow{a} & A \\ Ff \downarrow & & \downarrow f \\ FB & \xrightarrow{b} & B \end{array}$$

commutes.

Proposition 2.8.2. *F-algebras together with their homomorphisms form a category that we call $\text{Alg}(F)$.*

Proof. Identities and composition are inherited by the underlying category \mathcal{C} . We are left to show that the identities are homomorphisms:

$$\begin{array}{ccc} FA & \xrightarrow{a} & A \\ F id \downarrow & \circlearrowleft & \downarrow id \\ FA & \xrightarrow{a} & A \end{array}$$

and that homomorphisms are closed under composition:

$$\begin{array}{ccc}
 FA & \xrightarrow{a} & A \\
 \downarrow Ff & \circlearrowleft & \downarrow f \\
 FB & \xrightarrow{b} & B \\
 \downarrow Fg & \circlearrowleft & \downarrow g \\
 FC & \xrightarrow{c} & C
 \end{array}
 \begin{array}{l}
 F(g \circ f) \\
 g \circ f
 \end{array}$$

□

Example 2.8.3. Let us now consider the structure of the data types Nat and List as F-algebras:

1. **Nat:** Take $\mathcal{C} = \mathbf{Set}$ and $FX = 1 + X$, the F-algebras and their morphisms have the following form:

$$\begin{array}{ccc}
 1 + A & \xrightarrow{[c,h]} & A \\
 \downarrow !+f & & \downarrow f \\
 1 + B & \xrightarrow{[c',h']} & B
 \end{array}$$

Which is equivalent to:

$$\begin{array}{ccccc}
 1 & \xrightarrow{c} & A & \xrightarrow{h} & A \\
 & \searrow c' & \downarrow f & & \downarrow f \\
 & & B & \xrightarrow{h'} & B
 \end{array}$$

2. **List A:** Take $\mathcal{C} = \mathbf{Set}$ and $FX = 1 + A \times X$, where $A \in |\mathbf{Set}|$. The F-algebras and their morphisms take the following form:

$$\begin{array}{ccc}
 1 + A \times X & \xrightarrow{[c,h]} & X \\
 \downarrow !+id \times f & & \downarrow f \\
 1 + A \times Y & \xrightarrow{[c,h]} & Y
 \end{array}$$

Which again is equivalent to

$$\begin{array}{ccccc}
 1 & \xrightarrow{c} & A \times X & \xrightarrow{h} & X \\
 & \searrow c' & \downarrow id \times f & & \downarrow f \\
 & & A \times Y & \xrightarrow{h} & Y
 \end{array}$$

2.8.1 Initial F-algebras

Initial F-algebras (i.e. the initial object in $\text{Alg}(F)$) are of special interest to us. More concretely an F-algebra (I, i) is initial if for every (A, a) there exists a unique $\langle a \rangle : I \rightarrow A$ such that

$$\begin{array}{ccc} FI & \xrightarrow{i} & I \\ \downarrow F\langle a \rangle & & \downarrow \exists! \langle a \rangle \\ FA & \xrightarrow{a} & A \end{array}$$

commutes. We sometimes denote that initial F-algebra as μF .

The dual notion of *terminal F-algebra* is usually not of interest, since it is just inherited from \mathcal{C} :

$$\begin{array}{ccc} FA & \xrightarrow{a} & A \\ \downarrow F! & & \downarrow ! \\ F1 & \xrightarrow{!} & 1 \end{array}$$

Example 2.8.4. Important examples of initial F-algebras include:

1. In Example 2.8.3 (1) the data type *Nat* is the initial algebra together with the function *foldn* that we defined in the introduction. Where the following diagram expresses the defining equations for *foldn*:

$$\begin{array}{ccc} 1 + \text{Nat} & \xrightarrow{[\text{zero}, \text{succ}]} & \text{Nat} \\ \downarrow \text{id} + \text{foldn}(c, h) & & \downarrow \text{foldn}(c, h) \\ 1 + C & \xrightarrow{[c, h]} & C \end{array}$$

2. Similarly, in Example 2.8.3 (2) the data type *List A* is the initial algebra:

$$\begin{array}{ccc} 1 + A \times \text{List } A & \xrightarrow{[\text{nil}, \text{cons}]} & \text{List } A \\ \downarrow \text{id} + \text{foldr}(c, h) & & \downarrow \text{foldr}(c, h) \\ 1 + A \times C & \xrightarrow{[c, h]} & C \end{array}$$

We can now abstract the fusion and identity laws that we defined for each data type in section 1.2:

Proposition 2.8.5. *Let (I, i) be an initial F-algebra. The following holds:*

1. **Identity:** $\langle i \rangle = \text{id}_I : I \rightarrow I$,
2. **Fusion:** Let $f : (A, a) \rightarrow (B, b)$ be a homomorphism between F-algebras, then

$$\begin{array}{ccc} I & \xrightarrow{\langle a \rangle} & A \\ & \searrow \langle b \rangle & \downarrow f \\ & & B \end{array}$$

commutes.

Proof. Both follow by uniqueness of homomorphisms out of the initial object:

1. By uniqueness of homomorphisms $(I, i) \rightarrow (I, i)$
2. By uniqueness of homomorphisms $(I, i) \rightarrow (B, b)$

□

Proposition 2.8.6 (Lambeks Lemma). *Let (I, i) be an initial F -algebra. The F -algebra structure i is an isomorphism.*

Proof. Applying F on i yields another F -algebra (FI, Fi) , which induces a homomorphism $\langle Fi \rangle : I \rightarrow FI$. $\langle Fi \rangle$ is the inverse to i . Consider

$$\begin{array}{ccc}
 FI & \xrightarrow{i} & I \\
 \downarrow F\langle Fi \rangle & \circlearrowleft & \downarrow \langle Fi \rangle \\
 FFI & \xrightarrow{Fi} & FI \\
 \downarrow Fi & \circlearrowleft & \downarrow i \\
 FI & \xrightarrow{i} & I
 \end{array}$$

$F(i \circ \langle Fi \rangle)$ on the left and $i \circ \langle Fi \rangle$ on the right of the diagram.

from which we can follow that $i \circ \langle Fi \rangle = id_I : (I, i) \rightarrow (I, i)$ by uniqueness of the homomorphisms and thus also

$$\langle Fi \rangle \circ i = Fi \circ F\langle Fi \rangle = F(i \circ \langle Fi \rangle) = Fid_I = id_{FI}.$$

□

Example 2.8.7. Using Proposition 2.8.6, we can prove that not every functor F has an initial F -algebra. Consider the power set functor $\mathcal{P} : Set \rightarrow Set$. If there was an initial algebra $i : \mathcal{P}X \rightarrow X$, then $\mathcal{P}X \cong X$, which does not hold, because of Cantor's Theorem.

2.8.2 Term Algebras

2.8.3 Parametric Data Types

2.9 Functor Coalgebras

Coalgebras describe state based system by observations. Formally they are dual (we soon see in what sense) to F -algebras:

Definition 2.9.1 (F -Coalgebra). Let $F : \mathcal{C} \rightarrow \mathcal{C}$ be an endofunctor. An F -coalgebra is a pair $(C, c : C \rightarrow FC)$ and a homomorphism between coalgebras $h : (B, b) \rightarrow (C, c)$ is a morphism

$B \rightarrow C$ such that

$$\begin{array}{ccc} B & \xrightarrow{b} & FB \\ \downarrow h & & \downarrow Fh \\ C & \xrightarrow{c} & FC \end{array}$$

commutes.

Coalgebras together with their homomorphisms form a category that we call $\text{Coalg}(F)$. F-coalgebras and F-algebras are dual in the sense that $\text{Coalg}(F) = \text{Alg}(F^{op})^{op} \neq \text{Alg}(F)^{op}$, where $F^{op} : \mathcal{C}^{op} \rightarrow \mathcal{C}^{op}$.

This time we are interested in *terminal F-coalgebras* (T, t) , which are characterized by the fact that for any coalgebra (C, c) there exists a unique homomorphism such that

$$\begin{array}{ccc} C & \xrightarrow{c} & FC \\ \downarrow \llbracket c \rrbracket & & \downarrow F\llbracket c \rrbracket \\ T & \xrightarrow{t} & FT \end{array}$$

commutes. We sometimes denote the terminal F-algebra as νF .

Dual to F-algebras the *initial F-coalgebra* is trivial:

$$\begin{array}{ccc} 0 & \xrightarrow{i} & F0 \\ \downarrow i & & \downarrow Fi \\ C & \xrightarrow{c} & FC \end{array}$$

Example 2.9.2. Let us now consider some examples of (terminal) F-coalgebras. They describe state systems, thus we will describe the corresponding automaton.

1. Let $FX = X + 1 : \text{Set} \rightarrow \text{Set}$. Let Q be the state space, then state transitions of this system have the form $Q \xrightarrow{d} Q + 1$, i.e. an element $q \in Q$ either has a next state $d q \in Q$ or terminates, $d q \in 1$.

Homomorphisms are morphisms between state spaces that respect the state transitions d :

- $h d q = d' h q$,
- q terminates $\iff h q$ terminates,

which is expressed by the usual diagram:

$$\begin{array}{ccc} Q & \xrightarrow{d} & Q + 1 \\ \downarrow h & & \downarrow h+! \\ Q' & \xrightarrow{d'} & Q' + 1 \end{array}$$

The terminal F-coalgebra is $\mathbb{N}_\infty = \mathbb{N} \cup \{\infty\}$, with $t : \mathbb{N}_\infty \rightarrow 1 + \mathbb{N}_\infty$ defined by

$$t x := \begin{cases} \infty & \text{if } x = \infty \\ * \in 1 & \text{if } x = 0 \\ n & \text{if } x = n + 1 \end{cases}$$

and the unique homomorphism $h : (Q, d) \rightarrow (\mathbb{N}_\infty, t)$ returns the number of steps an element $q \in Q$ has to take until it terminates.

2. Let $FX = A \times X : \mathbf{Set} \rightarrow \mathbf{Set}$ for some set A . A coalgebra $Q \xrightarrow{\langle o, t \rangle} A \times Q$ returns for every $q \in Q$ an output $o q \in A$ and the next state $t q \in Q$.

Homomorphisms $h : (Q, \langle o, t \rangle) \rightarrow (Q', \langle o', t' \rangle)$ are mappings $h : Q \rightarrow Q'$ such that

- $o q = o' h q$,
- $h t q = t' h q$.

The terminal F-coalgebra is A^ω , i.e. the set of *streams* over A with

$$A^\omega \xrightarrow{\langle hd, tl \rangle} A \times A^\omega$$

defined by

$$(a_0, a_1, a_2, \dots) \mapsto (a_0, (a_1, a_2, \dots)).$$

The unique homomorphism $h : (Q, \langle o, t \rangle) \rightarrow (A^\omega, \langle hd, tl \rangle)$ maps a state $q \in Q$ to the stream

$$(o q, o(t q), o(t(t q)), \dots).$$

3. Recall that deterministic finite automata (DFA) are tuples $A = (Q, \Sigma, \delta, q_0, E)$ where
- Q is a state space,
 - Σ is a finite alphabet,
 - $\delta : Q \times \Sigma \rightarrow Q$ is a state transition function,
 - $q_0 \in Q$ is the initial state,
 - $E \subseteq Q$ is the set of accepting states.

By changing the type of δ via currying to $\delta : Q \rightarrow Q^\Sigma$ and representing E as a map $f : Q \rightarrow 2$, we can represent a DFA (without the initial state) as a map

$$Q \xrightarrow{\langle f, \delta \rangle} 2 \times Q^\Sigma.$$

Thus, we can represent DFA as coalgebras for $FX = 2 \times X^\Sigma : \mathbf{Set} \rightarrow \mathbf{Set}$. A homomorphism between automata

$$h : (Q \xrightarrow{\langle f, \delta \rangle} 2 \times Q^\Sigma) \rightarrow (Q' \xrightarrow{\langle f', \delta' \rangle} 2 \times Q'^{\Sigma'})$$

is then a mapping $h : Q \rightarrow Q'$ such that

$$h(\delta(a, q)) = \delta'(a, h q).$$

The terminal F-coalgebra is $2^{\Sigma^*} \cong \mathcal{P}(\Sigma^*)$, i.e. the set of formal languages over Σ with the structure $\langle \varepsilon?, \partial \rangle : \mathcal{P}(\Sigma^*) \rightarrow 2 \times \mathcal{P}(\Sigma^*)$ defined by

$$\varepsilon?(L) = \begin{cases} 1 & \varepsilon \in L \\ 0 & \text{else} \end{cases}$$

and

$$\partial(L)(a) = a^{-1}L = \{w \mid aw \in L\}.$$

Finally, the unique homomorphism $h : Q \rightarrow \mathcal{P}(\Sigma^*)$ returns for any $q \in Q$ the formal language that is accepted by q .

Proposition 2.9.3. Let $T \xrightarrow{t} FT$ be a terminal F -coalgebra, then t is an isomorphism.

Proof. Follows by duality from Proposition 2.8.6. □

2.9.1 Corecursion and Coinduction

Corecursion is a proof principle: each F -coalgebra (C, c) induces a unique homomorphism $h : (C, C) \rightarrow (\nu F, t)$.

Example 2.9.4. Let us consider some functions defined by corecursion:

1. Recall $A^\omega \xrightarrow{\langle hd, tl \rangle} A \times A^\omega$, we can define a function $zip : A^\omega \times A^\omega \rightarrow A^\omega$ by

$$hd(zip \ \sigma \ \tau) = hd \ \sigma; \quad tl(zip \ \sigma \ \tau) = zip \ \tau \ (tl \ \sigma).$$

This definition corresponds to the following coalgebra structure:

$$\begin{array}{ccc} A^\omega \times A^\omega & \xrightarrow{\langle hd \circ \pi_1, \langle \pi_2, tl \circ \pi_1 \rangle \rangle} & A \times (A^\omega \times A^\omega) \\ \downarrow zip & & \downarrow id \times zip \\ A^\omega & \xrightarrow{\langle hd, tl \rangle} & A \times A^\omega \end{array}$$

2. Similarly, for $f : A \rightarrow B$ we can define $map \ f : A^\omega \rightarrow B^\omega$ by

$$hd(map \ f \ as) = f(hd \ as); \quad tl(map \ f \ as) = map \ f \ (tl \ as),$$

which corresponds to the coalgebra structure:

$$\begin{array}{ccc} A^\omega & \xrightarrow{\langle hd, tl \rangle} & A \times A^\omega \\ \downarrow map \ f & & \downarrow id \times map \ f \\ B^\omega & \xrightarrow{\langle hd, tl \rangle} & B \times B^\omega \end{array}$$

Coinduction is a proof principle for showing *behavioral equivalence*.

Definition 2.9.5 (Behavioral equivalence). Let $F : \mathbf{Set} \rightarrow \mathbf{Set}$. Two elements of coalgebras $x \in (C, c), y \in (D, d)$ are called behavioral equivalent “ $x \sim y$ ” if there exist

$$(C, c) \xrightarrow{h} (E, e) \xleftarrow{k} (D, d),$$

such that $h \ x = k \ y$.

Remark 2.9.6. If νF exists then

$$x \sim y \iff h_c \ x = h_d \ y,$$

where $h_c : (C, c) \rightarrow (\nu F, t)$, $h_d : (D, d) \rightarrow (\nu F, t)$ are the unique morphisms into the terminal coalgebra. The proof of “ \Leftarrow ” is clear, for “ \Rightarrow ” consider the diagram:

$$\begin{array}{ccccc}
 (C, c) & \xrightarrow{h} & (E, e) & \xleftarrow{k} & (D, d) \\
 & \searrow h_c & \downarrow h_e & \swarrow h_d & \\
 & & (\nu F, t) & &
 \end{array}$$

Example 2.9.7. As a consequence of the previous remark, we can follow that for $FX = 2 \times X^\Sigma$ the following holds:

$$x \sim y \iff x, y \text{ accept the same form language.}$$

Definition 2.9.8 (Bisimulation). Let $F : \mathbf{Set} \rightarrow \mathbf{Set}$ and let $(C, c), (D, d)$ be F -coalgebras. A *bisimulation* is a relation $R \subseteq C \times D$ such that a coalgebra (R, r) exists where

$$\begin{array}{ccccc}
 C & \xleftarrow{\pi_1} & R & \xrightarrow{\pi_2} & D \\
 \downarrow c & & \downarrow r & & \downarrow d \\
 FC & \xleftarrow{F\pi_1} & FR & \xrightarrow{F\pi_2} & FD
 \end{array}$$

commutes. Two elements $c \in C, d \in D$ are called *bisimilar* if there exists a bisimulation R such that cRd holds.

Proposition 2.9.9.

$$x, y \text{ bisimilar} \Rightarrow x \sim y$$

Example 2.9.10. Let us examine bisimilarity of streams, i.e. consider the functor $FX = A \times X$ and coalgebras

$$C \xrightarrow{\langle h, t \rangle} A \times C; \quad D \xrightarrow{\langle h', t' \rangle} A \times D.$$

A relation $R \subseteq C \times D$ is a bisimulation if

- $h x = h' y$,
- $x R y \Rightarrow (t x) R (t' y)$.

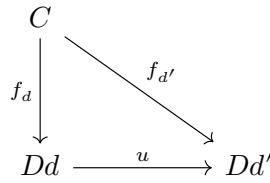

2.10 Limits

Limits are an abstraction of products and many other categorical concepts.

Definition 2.10.1 (Limit). We will need to introduce some related notions first.

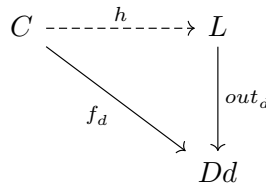

1. A *diagram* in \mathcal{C} is a functor $D : \mathcal{D} \rightarrow \mathcal{C}$, where \mathcal{D} is small.
2. A *cone* of a diagram $D : \mathcal{D} \rightarrow \mathcal{C}$ consists of

- an object $C \in |\mathcal{C}|$ called the *apex* and
- a family of morphisms $(f_d : C \rightarrow Dd)_{d \in |\mathcal{D}|}$ such that

commutes for every $u : d \rightarrow d'$.

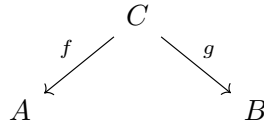

3. A *limit* of a diagram D is a universal cone, i.e. a cone (L, out_d) such that for every cone (C, f_d) there exists a unique morphism $h : C \rightarrow L$ such that $out_d \circ h = f_d$ for all $d \in |\mathcal{D}|$:

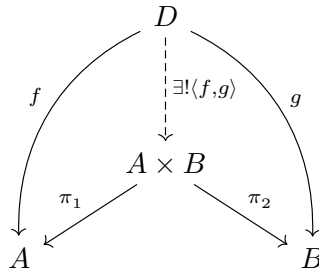

The notion of limit can be instantiated to many interesting notions:

Definition 2.10.2 (Terminal object (as limit)). Let \mathcal{D} be the empty category \emptyset . Diagrams of \mathcal{D} are empty and thus cones consist of just the apex $C \in |\mathcal{C}|$. This also means that every object in \mathcal{C} forms a cone for this diagram. The limit $1 \in |\mathcal{C}|$ is thus the terminal object, since for any $C \in |\mathcal{C}|$ there is a unique morphism $! : C \rightarrow 1$.

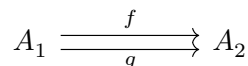

Definition 2.10.3 (Product (as limit)). Let \mathcal{D} be the discrete category with 2 elements. Diagrams D are pairs (A, B) of objects of \mathcal{C} , cones are pairs of morphisms

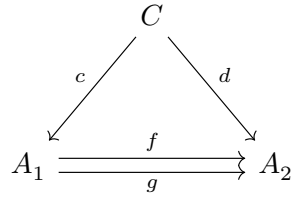

and limits of such diagrams are exactly products:

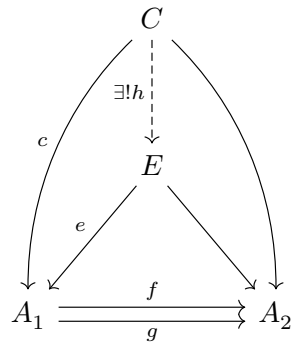

Definition 2.10.4 (Equalizer). Let \mathcal{D} be a category with two non-trivial and parallel morphisms $u, v : 1 \rightarrow 2$. Diagrams are parallel morphisms

and cones are pairs of morphisms $c : C \rightarrow A_1, d : C \rightarrow A_2$, such that $f \circ c = d = g \circ c$:

A limit of such a diagram is called an *equalizer* of f and g :

where the unnamed morphisms are usually omitted.

Definition 2.10.5 (Regular Monomorphism). A monomorphism is called *regular* if it is also an equalizer.

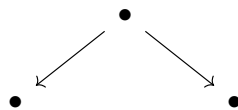

Proposition 2.10.6. *Every equalizer is a monomorphism and thus a regular monomorphism.*

Proof. □

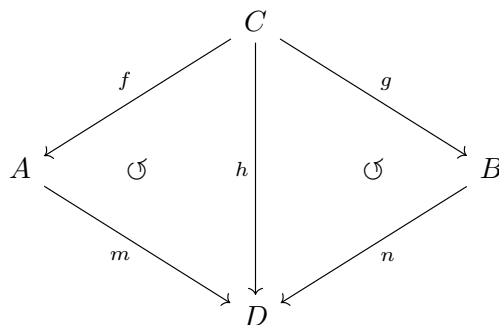

Proposition 2.10.7. e is a regular monomorphism and an epimorphism $\iff e$ is an isomorphism.

Proof. □

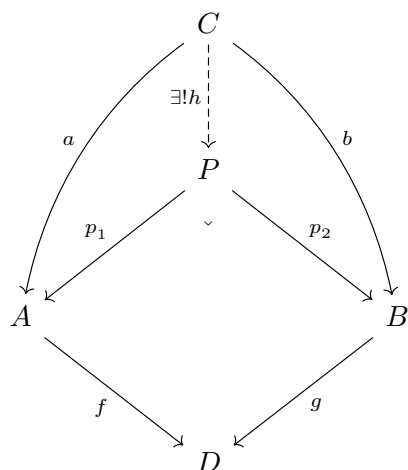

Definition 2.10.8 (Pullback). Let \mathcal{D} be a poset category illustrated by the following diagram:

Diagrams consist of two arrows with the same codomain. Cones are of the form:

where h is usually omitted, and instead the condition is expressed as $m \circ f = n \circ g$. Limits of such diagrams are called *pullbacks* usually denoted in the following way:

Proposition 2.10.9. *Limits are unique up to isomorphism.*

Proof.

□

Definition 2.10.10 (Complete Category). A category \mathcal{C} is called *complete* if every diagram in \mathcal{C} has a limit.

Proposition 2.10.11. *\mathcal{C} is complete iff \mathcal{C} has all products and equalizers, i.e. using products and equalizer one can construct arbitrary limits.*

Proof.

□

Definition 2.10.12 (Finitely Complete Category). A category \mathcal{C} is called *finitely complete* if every finite diagram in \mathcal{C} has a limit.

Proposition 2.10.13. *The following are equivalent:*

1. \mathcal{C} is finitely complete
2. \mathcal{C} has finite products and equalizers
3. \mathcal{C} has finite products and pullbacks
4. \mathcal{C} has a terminal object and pullbacks

Proof.

□

2.11 Colimits

3 Constructions

3.1 CPO

Recall that $FI \cong I$ for the initial F-algebra I , our goal is to construct initial F-algebras as least fixpoints. Consider for example the faculty function which is defined by the recursive equation

$$fac\ n := \text{if } n = 0 \text{ then } 1 \text{ else } n \cdot fac(n - 1).$$

$fac : \mathbb{N} \rightarrow \mathbb{N}$ is the *solution* of the previous equation or equivalently the fixpoint of the function $\varphi : \text{Par}(\mathbb{N}, \mathbb{N}) \rightarrow \text{Par}(\mathbb{N}, \mathbb{N})$ defined by

$$\varphi\ f\ n := \text{if } n = 0 \text{ then } 1 \text{ else } n \cdot f(n - 1).$$

Thus, fac should satisfy $fac = \varphi(fac)$, which is obtained by iteration of φ :

	0	1	2	...
\perp				
$\varphi(\perp)$	1			
$\varphi(\varphi(\perp))$	1	1		
$\varphi(\varphi(\varphi(\perp)))$	1	1	2	
...				

Since $\text{Par}(\mathbb{N}, \mathbb{N})$ admits a poset structure where $f \sqsubseteq g$ iff $\text{dom } f \subseteq \text{dom } g$ and $\forall x \in \text{dom } f. fx = gx$, we can view fac as the supremum of the ascending chain

$$\perp \sqsubseteq \varphi(\perp) \sqsubseteq \varphi(\varphi(\perp)) \sqsubseteq \dots$$

Definition 3.1.1 (Complete Partial Order). A *complete partial order* (CPO) is a poset (X, \sqsubseteq) with

1. the smallest element \perp ,
2. suprema for infinite chains:

$$x_0 \sqsubseteq x_1 \sqsubseteq x_2 \sqsubseteq \dots$$

We denote the supremum of such chains as $\bigsqcup_i x_i$.

Example 3.1.2. Examples of CPOs include:

1. Every set X yields a CPO $(\mathcal{P}X, \subseteq)$, where the smallest element is \emptyset and the supremum of chains is the big union.
2. For any X, Y we get a CPO $(\text{Par}(X, Y), \sqsubseteq)$, defined as above. The supremum of a chain (f_i) is defined by

$$\text{dom}(\bigsqcup_i f_i) = \bigcup_i \text{dom } f_i; \quad (\bigsqcup_i f_i)(x) = f_i(x), \text{ for a suitable (big enough) } i.$$

3 Constructions

3. Every set X yields a CPO (X_{\perp}, \sqsubseteq) , where $X_{\perp} = X \cup \{\perp\}$ and $x \sqsubseteq y$ iff $x = y$ or $x = \perp$. This is called the *flat CPO*.

Definition 3.1.3 (Continuous Function). A function $\varphi : (X, \sqsubseteq) \rightarrow (X', \sqsubseteq')$ is called *continuous* if

- φ is monotonous, i.e. $x \sqsubseteq y \Rightarrow \varphi(x) \sqsubseteq' \varphi(y)$,
- φ preserves suprema of chains, i.e. $\varphi(\bigsqcup x_i) = \bigsqcup' \varphi(x_i)$.

Example 3.1.4. The aforementioned $\varphi : \text{Par}(\mathbb{N}, \mathbb{N})$ with $\varphi f n = \text{if } n = 0 \text{ then } 1 \text{ else } n$ is continuous.

Theorem 3.1.5 (Kleene's Fixpoint Theorem). Let (X, \sqsubseteq) be a CPO and let $\varphi : X \rightarrow X$ be continuous. The least fixpoint of φ is

$$\mu\varphi = \bigsqcup_i \varphi^i(\perp).$$

Proof. $\mu\varphi$ is a fixpoint, since

$$\varphi(\mu\varphi) = \varphi(\bigsqcup_i \varphi^i(\perp)) = \bigsqcup_i \varphi^{i+1}(\perp) = \bigsqcup_i \varphi^i(\perp) = \mu\varphi.$$

To show that it is the least fixpoint, consider another fixpoint $\varphi(x) = x$. To show that $\mu\varphi \sqsubseteq x$ it suffices to show that $\varphi^i(\perp) \sqsubseteq x$ for all $i \in \mathbb{N}$, which indeed follows by induction:

Case 1. $i = 0$

$$\varphi^0(\perp) = \perp \sqsubseteq x$$

Case 2. $i = n + 1$

The induction hypothesis $\varphi^n \sqsubseteq x$ directly implies

$$\varphi^{n+1}(\perp) \sqsubseteq \varphi(x) = x$$

by monotonicity of φ . □

In the next section we will generalize this result categorically to obtain a construction for initial F-algebras.

3.2 Initial Algebra Construction

Consider a cocomplete category \mathcal{C} , \mathcal{C} has similarities to a CPO, since it has

- an initial object $0 \xrightarrow{i_A} A$,
- colimits of every ω -chain of morphisms (i.e. diagrams $D : (\mathbb{N}, \leq) \rightarrow \mathcal{C}$):

$$\begin{array}{ccccccc}
 A_0 & \xrightarrow{a_{0,1}} & A_1 & \xrightarrow{a_{1,2}} & A_2 & \xrightarrow{\dots} & \dots \\
 & \searrow & \downarrow \iota_1 & \nearrow & \searrow & \nearrow & \\
 & & C & & & &
 \end{array}$$

ι_0 (curved arrow from A_0 to C), ι_2 (curved arrow from A_2 to C), and \dots (curved arrow from \dots to C)

Definition 3.2.1 (ω -cocontinuity). A functor $F : \mathcal{C} \rightarrow \mathcal{C}$ is called ω -cocontinuous if F preserves colimits of ω -chains, i.e. if for every diagram $D : (\mathbb{N}, \leq) \rightarrow \mathcal{C}$:

$$F(\operatorname{colim} D) \cong \operatorname{colim}(FD).$$

More concretely, if for every colimit (C, ι) of D , the cone $(FC, F\iota)$ is the colimit of FD .

Definition 3.2.2 (Finitary Functor). A functor $F : \mathbf{Set} \rightarrow \mathbf{Set}$ is called *finitary* if for every X and $x \in FX$ there exists a finite surjective map $m : Y \rightarrow X$ and $y \in FY$ such that $x = F m y$.

Theorem 3.2.3. *Finitary functors are ω -cocontinuous.*

Lemma 3.2.4. *Finitary functors are closed under*

1. *finite products,*
2. *coproducts,*
3. *and composition.*

A consequence of Lemma 3.2.4 is that for any signature Σ , the functor

$$F_{\Sigma}X = \prod_{\sigma \in \Sigma} X^{ar(\sigma)}$$

is finitary.

Theorem 3.2.5. *Let \mathcal{C} be cocomplete and $F : \mathcal{C} \rightarrow \mathcal{C}$ σ -cocontinuous. Then F has the initial algebra $I = \operatorname{colim}_{n \in \mathbb{N}} F^n 0$. More concretely I is the colimit of the ω -chain:*

$$\begin{array}{ccccccc}
 0 & \xrightarrow{i} & F0 & \xrightarrow{Fi} & FF0 & \xrightarrow{\dots} & \dots \\
 & \searrow & \downarrow \iota_1 & \nearrow & & & \\
 & & I & & & & \\
 & \swarrow \iota_0 & & \nwarrow \iota_2 & & \swarrow \dots & \\
 & & & & & &
 \end{array}$$
